## (57) Abstract

The present invention discloses steroid/thyroid hormone receptor DNA binding domain compositions that determine target gene specificity. The invention further discloses methods converting the target gene specificity of one receptor into the target gene specificity of another. Still further the invention discloses novel assays for identifying ligands for orphan hormone receptors. These assays are especially useful since they avoid the necessity of constructing chimeric genes and proteins in order to search for ligands that can activate a putative receptor.

HORMONE RESPONSE ELEMENT  
COMPOSITIONS AND ASSAY

FIELD OF THE INVENTION

5           The present invention relates generally to  
hormone receptor genes and proteins. More particularly,  
the present invention relates to identification and  
characterization of determinants that govern target gene  
specificity for the superfamily of steroid/thyroid  
10 hormone receptors. In addition the invention relates to  
novel assays for identifying ligands for "orphan"  
hormone receptors.

BACKGROUND OF THE INVENTION

15           The steroid/thyroid hormone receptors form a  
superfamily of ligand-dependent transcription factors  
that influence cell function and fate in eukaryotes. It  
is known that these receptors transduce extracellular  
hormonal signals to target genes that contain specific  
enhancer sequences referred to as hormone-response  
20 elements (HREs) (Evans 1988; Green and Chambon 1988).  
It is also known that each receptor recognizes its own  
HREs, thus assuring that a distinct response is  
triggered by different hormones.

25           Sequence comparisons and mutational analyses of  
glucocorticoid receptor (GR) have identified functional  
domains responsible for transcriptional activation and  
repression, nuclear localization, DNA binding, and  
hormone binding (Giguer, et al., 1986; Hollenberg, et  
al., 1987; Rusconi, et al., 1987; Picard and Yamamoto,  
30 1987; Hollenberg and Evans, 1988; Oro, et al., 1988a).  
The DNA binding domain, which is required to activate  
transcription, consists of 66-68 amino acids of which  
about 20 sites, including nine cysteines (C<sub>1</sub> to C<sub>9</sub>), are  
invariant among different receptors (Fig. 1a). The  
35 modular structure of members of this receptor super-

family allows the exchange of one domain for another to create functional chimera. This strategy was used to demonstrate that the DNA binding domain is solely responsible for the specific recognition of the HRE in vivo (Green and Chambon, 1987; Giguere, et al., 1987; Petkovich, et al., 1987; Kumar, et al., 1987; Umesono, et al., 1988; Thompson, et al., 1989) and in vitro (Kumar and Chambon, 1988).

By analogy with the proposed structure for *Xenopus* transcription factor TFIIIA (Miller, et al., 1985), the invariant cysteines are thought to form two "zinc fingers" for specific DNA binding. In a polypeptide encompassing the DNA binding domain of rat GR, it has been shown that each of two Zn(II) is coordinated in a tetrahedral arrangement by four cysteines (Freedman, et al., 1988). Involvement of these cysteines in Zn(II) coordination is also supported by the fact that eight out of nine cysteines, enough to chelate two Zn(II), are required for the receptor function revealed by point mutagenesis experiments (Hollenberg, et al., 1988; Severne, et al., 1988).

Functional models have been proposed in an attempt to coordinate research results with gene regulation mechanisms that function in vivo. As those skilled in the art will know, one such model for the DNA binding domain is "zinc finger model". (A predicted "finger" structure is presented in Fig. 1b; also see Severne, et al., 1988.) In this model, the first four cysteines (C<sub>1</sub> to C<sub>4</sub>) chelate one Zn(II) to form Finger 1, which includes a loop of 13 amino acids between C<sub>2</sub> and C<sub>3</sub>. Finger 2 is formed by the next four cysteines (C<sub>5</sub> to C<sub>8</sub>), since function is retained when the ninth cysteine is changed to an alanine or serine (Severne, et al., 1988). Finger 2 has a loop of 9 amino acids, and is separated by a "Linker" of 15-17 amino acids from Finger 1. Both fingers are functionally required because

As the present invention discloses, functional  
20 characterization of mutant receptors carrying chimeric  
DNA binding domains has made it possible to dissect  
molecular determinants of target gene specificity for  
GR, ER, and TR. For example, as th present invention  
discloses, the identity of GR DNA binding domain can be  
25 converted into those of ER and TR by changing three and  
eight amino acids, respectively. The present invention  
also discloses that a single Gly to Glu change in the  
first "zinc finger" of the GR receptor produces a  
receptor with dual HRE (i.e., GRE and ERE) sequence  
30 responsiveness. These discoveries localize two  
structural determinants of target gene specificity and  
suggest a simple pathway for the co-evolution of  
receptor DNA binding domains and regulatory networks.

These discoveries also make it possible to  
35 convert one receptor into another, and to create  
engineered receptors that have desired HRE recognition

---

features. They have also enabled the development of assays that are useful for identifying ligands for "orphan" hormone receptors. Such assays are especially advantageous because they eliminate the necessity of constructing chimeric genes and proteins in order to search for ligands that can activate the orphan receptors.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The following is a brief description of the drawings. More detailed descriptions are found in the section of the specification labeled, "Detailed Description of the Drawings".

FIGURE 1 (a-c) is a schematic drawing. Fig. 1a shows a comparison of amino acid sequences among the DNA binding domains of hGR, hT<sub>3</sub>β, and hER. Fig. 1b shows predicted zinc fingers based on those for rat GR18. Fig. 1c shows the structures of optimized hormone response elements for GR (GRE), ER (ERE), and T<sub>3</sub>R (TRE).

FIGURE 2 (a and b) is a schematic drawing that illustrates transactivation of luciferase reporter plasmids by mutant receptors.

FIGURE 3 is a schematic drawing that illustrates identification of two distinct elements specifying the TREp+ and ERE+ phenotypes.

FIGURE 4 (a-f) is comprised of the combination of a schematic drawing and photographs of blots. Fig. 4 shows induction of CAT activities by mutant receptors from the basal ΔMTV-CAT (ΔM), T<sub>3</sub>-responsive ΔMTV-TREp-CAT (TREp), an estrogen-responsive ΔMTV-ERE-CAT (ERE) reporters.

#### DEFINITIONS

In the present specification and claims, reference will be made to phrases and terms of art which are expressly defined for use herein as follows:

As used herein, species are identified as follows: h, human; r, rat; m, mouse; c, chicken; and d, *Drosophila*.

As used herein, "steroid hormone superfamily of receptors" refers to the class of related receptors comprised of glucocorticoid, mineralocorticoid, progesterone, estrogen, estrogen-related, vitamin D<sub>3</sub>, thyroid, v-erb-A, retinoic acid and E75 (*Drosophila*) receptors. See Evans (1988) and the references cited therein.

As used herein, GR means glucocorticoid receptor. The DNA referred to as hGR codes for human glucocorticoid receptor GR. hGR is encoded by plasmid pRShGR which has been deposited for patent purposes and accorded ATCC No. 67200.

As used herein, MR means mineralocorticoid receptor. The DNA referred to as hMR codes for human mineralocorticoid receptor MR. hMR is encoded by plasmid pRShMR which has been deposited for patent purposes and accorded ATCC No. 67201.

As used herein, TR means thyroid receptor and T<sub>3</sub>R means triiodothyronine (T<sub>3</sub>) receptor. TR $\alpha$  and TR $\beta$  refer to the alpha and beta forms of the thyroid receptor. Plasmid pherb-A 8.7 encodes hTR $\alpha$ ; it has been deposited for patent purposes and accorded ATCC No. 40374. Plasmid pEA101 encodes hTR $\beta$ ; it has been deposited for patent purposes and accorded ATCC No. 67244.

As used herein, ERR means estrogen-related receptor. The acronyms, hERR1 and hERR2 refer to human estrogen-related receptors 1 and 2. These receptors are more related to steroid receptors than to the thyroid receptors, yet they do not bind any of the major classes of known steroid hormones (Giguere, et al., 1988). hERR1 is encoded by plasmids pE4 and pHKA, which have been deposited for patent purposes and accorded ATCC No. 67309 and 67310, respectively. (Neither pE4 or pHKA are

complet clones; hERR1 is constructed by joining segments from both clones.) hERR2 is encoded by plasmid pH3 which has been deposited for patent purposes and accorded ATCC No. 40373.

5 As used herein, RAR means retinoic acid receptor. The acronym, hRAR $\alpha$ , refers to human retinoic acid receptor  $\alpha$ . hRAR $\alpha$  is encoded by plasmid pHRAR $\alpha$  which has been deposited for patent purposes and accorded ATCC No. 40392.

10 As used herein, VDR means vitamin D<sub>3</sub> receptor.

As used herein, an "orphan" receptor is a protein encoded by a DNA sequence that is homologous with DNA sequences that encode known members of the steroid/thyroid superfamily of hormone receptors. The  
15 term "orphan" denotes the fact that the ligand(s) which bind to the putative receptor are not yet known.

As used herein, element P means one of two clusters of amino acids in the steroid/thyroid receptors that can differentially control target gene specificity  
20 of the DNA binding domains. The cluster of amino acids that comprise element P for the GR subfamily (GR, MR, PR, AR) is "GSCKV"; the clusters that comprise element P for the ER subfamily (T<sub>3</sub>R $\alpha$ , T<sub>3</sub> $\alpha$ , RAR $\alpha$ , RAR $\beta$ , VD<sub>3</sub>R, NGFIB, TR<sub>2</sub>, v-erbA, ear2, ear3, Knirps, Knirps-related, ERR1,  
25 ERR2) are "EGCKA", "EGCKG", "EGCKS", and "EACKA". Also see Table 2.

As used herein, element D means one of two clusters of amino acids in the steroid/thyroid receptors that can differentially control target gene specificity  
30 of the DNA binding domains. The clusters of amino acids that comprise element D for the GR subfamily (GR, MR, PR, AR) are "AGRND" and "ASRND"; the clusters that comprise element P for the ER subfamily (T<sub>3</sub>R $\alpha$ , T<sub>3</sub> $\alpha$ , RAR $\alpha$ , RAR $\beta$ , VD<sub>3</sub>R, NGFI-B, TR<sub>2</sub>, v-erbA, ear2, ear3, Knirps, Knirps-related, ERR1, ERR2) are "PATNQ", "KYDSC",  
35 "KYEKG", "HRDKN", "PFNGD", "LANKD", "RGSKD", "TYDGC",

"RSNRD", "RANRN", "KNEGK", "KNNGE", "PASNE", and "PATNE". Also see Table 2.

As used herein, CAT means chloramphenicol acetyltransferase.

5 As used herein, luciferase means firefly luciferase. See, de Wet, et al., (1987).

As used herein, COS means monkey kidney cells which express T antigen (Tag). See Gluzman, Cell, 23:175 (1981). As used herein, CV-1 means mouse kidney  
10 cells from the cell line referred to as "CV-1". CV-1 is the parental line of COS. Unlike COS cells, which have been transformed to express SV40 T antigen (Tag), CV-1 cells do not express T antigen. CV-1 cells are receptor-deficient cells that are also useful in the  
15 assays of the present invention.

As used herein, HRE means hormone response element. HREs are short cis-acting sequences (about 20 bp in size) that are required for hormonal (or ligand) activation of transcription. The attachment of these  
20 elements to an otherwise hormone-nonresponsive gene causes that gene to become hormone responsive. HREs function in a position- and orientation-independent fashion. Unlike other enhancers, the activity of the HREs is dependent upon the presence or absence of  
25 ligand. See Evans (1988) and the references cited therein.

As used herein, engineered HREs refer to HREs that have been recombinantly produced using genetic engineering techniques such as nucleotide substitution,  
30 deletion, etc. If wild-type, engineered or synthetic HREs are linked to hormone-nonresponsive promoters, these promoters become hormone responsive. See Evans (1988) and the references cited therein.

As used herein, synthetic HREs refer to HREs  
35 that have been synthesized in vitro using automated nucleotide synthesis machines. Since the HREs are only

about 20 bp in size, they are easily synthesized in this manner. If wild-type, engineered or synthetic HREs are linked to hormone-nonresponsive promoters, these promoters become hormone responsive. See Evans (1988) and the references cited therein.

As used herein, the acronym GRE means glucocorticoid response element and TRE means thyroid receptor response element. GREs are hormone response elements that confer glucocorticoid responsiveness via interaction with the GR. See Payvar, et al., *Cell*, 35:381 (1983) and Schiedereit, et al., *Nature*, 304:749 (1983). GREs can be used with any wild-type or chimeric receptor whose DNA-binding domain can functionally bind (i.e., activate) with the GRE. For example, since GR, MR and PR receptors can all activate GREs, a GRE can be used with any wild-type or chimeric receptor that has a GR, MR or PR-type DNA-binding domain. TREs are similar to GREs except that they confer thyroid hormone responsiveness via interaction with TR. TREs can be used with any wild-type or chimeric receptor whose DNA-binding domain can functionally bind (i.e., activate) with the TRE. Both TR and RR receptors can activate TREs, so a TRE can be used with any receptor that has a TR or RR-type DNA-binding domain.

As used herein, ligand means an inducer, such as a hormone or growth substance. Inside a cell the ligand binds to a receptor protein, thereby creating a ligand/receptor complex, which in turn can bind to an appropriate hormone response element. Single ligands may have multiple receptors. For example, both the  $T_3R\alpha$  and the  $T_3R\beta$  bind thyroid hormone such as  $T_3$ .

As used herein, the word "operative", in the phrase "operative hormone response element functionally linked to a ligand-responsive promoter and an operative reporter gene", means that the respective DNA sequences (represented by the terms "hormone response element",

"ligand-responsive promoter" and "reporter gene") are operational, i.e., the hormone response element can bind with the DNA-binding domain of receptor protein (either wild-type or chimeric), the ligand-responsive promoter can control transcription of the reporter gene (upon appropriate activation by a HRE/receptor protein/ligand complex) and the reporter gene is capable of being expressed in the host cell. The phrase "functionally linked" means that when the DNA segments are joined, upon appropriate activation, the reporter gene (e.g., CAT or luciferase) will be expressed. This expression occurs as the result of the fact that the "ligand responsive promoter" (which is downstream from the hormone response element, and "activated" when the HRE binds to an appropriate ligand/receptor protein complex, and which, in turn then "controls" transcription of the reporter gene) was "turned on" or otherwise activated as a result of the binding of a ligand/receptor protein complex to the hormone response element.

As used herein, the phrase "DNA-binding domain" of receptors refers to those portions of the receptor proteins (such as glucocorticoid receptor, thyroid receptor, mineralocorticoid receptor, estrogen-related receptor and retinoic acid receptor) that bind to HRE sites on the chromatin DNA. The boundaries for these DNA-binding domains have been identified and characterized for the steroid hormone superfamily. See Evans, (1988); also see Giguere, et al., (1986); Hollenberg, et al., (1987); Green and Chambon (1987); Miesfield, et al., (1987); and Evans (1988).

The DNA-binding domains of the steroid hormone superfamily of receptors consist of an amino segment varying between 66 to 68 amino acids in length. This segment contains 9 cysteine residues, one of which is the first amino acid of the segment. This first Cys residue begins a motif described as Cys-X<sub>2</sub>-Cys-X<sub>13-15</sub>-Cys-

X<sub>2</sub>-Cys, where X is any amino acid residue. The DNA-binding domain invariably ends with the amino acids Gly-Met.

As used herein, the phrase "ligand-binding domain region" of receptors refers to those portions of the receptor proteins that bind to ligands such as growth substances or the hormones. These boundaries of the ligand-binding domains for the steroid receptor superfamily have been identified and characterized. See Evans (1988).

As used herein, "mutating" means using genetic engineering techniques to alter DNA so that it is different from the "wild-type" or unmodified sequences. Useful genetic engineering techniques for altering the DNA include, but are not limited to, insertion of new nucleotides into wild-type sequences, deletion of nucleotides from wild-type sequences, and substitution of nucleotides in the wild-type sequences, for example by site directed mutagenesis.

As used herein, "mutant" DNA of the invention refers to DNA that has been genetically engineered to be different from the "wild-type" or unmodified sequences. Such genetic engineering includes insertion of new nucleotides into wild-type sequences, deletion of nucleotides from wild-type sequences, or substitution of nucleotides in the wild-type sequences, for example by site directed mutagenesis.

Use of the term "substantial sequence homology" in the present specification and claims means it is intended that DNA, RNA, or amino acid sequences which have slight and non-consequential sequence variations from the actual sequences disclosed and claimed herein are within the scope of the appended claims. In this regard, the "slight and non-consequential" sequence variations mean that the homologous sequences will be functionally equivalent to the sequences of the

invention, i.e., the homologous sequences function in substantially the same manner to produce substantially the same compositions as the nucleic acid and amino acid compositions disclosed and claimed herein.

5 As used herein, the term "recombinantly produced" means made using genetic engineering techniques, not merely purified from nature.

The amino acids which comprise the various amino acid sequences appearing herein may be identified  
10 according to the following three-letter or one-letter abbreviations:

<u>Amino Acid</u>	<u>Three-Letter Abbreviation</u>	<u>One Letter Abbreviation</u>
L - Alanine	Ala	A
15 L - Arginine	Arg	R
L - Asparagine	Asn	N
L - Aspartic Acid	Asp	D
L - Cysteine	Cys	C
L - Glutamine	Gln	Q
20 L - Glutamic Acid	Glu	E
L - Glycine	Gly	G
L - Histidine	His	H
L - Isoleucine	Ile	I
L - Leucine	Leu	L
25 L - Lysine	Lys	K
L - Methionine	Met	M
L - Phenylalanine	Phe	F
L - Proline	Pro	P
L - Serine	Ser	S
30 L - Threonine	Thr	T
L - Tryptophan	Trp	W
L - Tyrosine	Tyr	Y
L - Valine	Val	V

35 Th nucl otides which comprise th various nucleotide sequences appearing herein have their

usual single-letter designations (A, G, T, C or U) used routinely in the art.

As used herein, bp means base pairs and kb means kilobase pairs.

5 In the present specification and claims, the Greek letters alpha ( $\alpha$ ), beta ( $\beta$ ), gamma ( $\gamma$ ), etc., are sometimes referred to as a, b, g, etc.

In the present specification and claims, unless noted otherwise, temperatures are in degrees  
10 Centigrade.

#### DEPOSITS

Plasmids pRShGR (hGR), pRShMR (hMR), pEA101 (Ht<sub>3</sub> $\beta$ ) and GMCAT, all of which are in *E. coli* HB101, plus plasmids pE4 and pHKA (which together encode  
15 hERR1), pH3 (hERR2), pherb-A 8.7 (hTR $\alpha$ , pHFA 8 (a partial clone of hTR $\alpha$ , and plasmid phRAR $\alpha$  have been deposited at the American Type Culture Collection, Rockville, Maryland, U.S.A. (ATCC) under the terms of  
20 the Budapest Treaty on the International Recognition of Deposits of Microorganisms for Purposes of Patent Procedure and the Regulations promulgated under this Treaty. Samples of the plasmids are and will be available to industrial property offices and other persons legally entitled to receive them under the  
25 terms of said Treaty and Regulations and otherwise in compliance with the patent laws and regulations of the United States of America and all other nations or international organizations in which this application, or an application claiming priority of  
30 this application, is filed or in which any patent granted on any such application is granted.

The ATCC Deposit Numbers and Deposit Dates for the deposits are as follows:

	pRShGR (hGR)	67200	Sept. 9, 1986
35	pRShMR (hMR)	67201	Sept. 9, 1986
	pE4 (hERR1*)	67309	Jan. 30, 1987

	phHKA (hERR1*)	67310	Jan. 30, 1987
	phH3 (hERR2)	40373	Sept. 29, 1987
	GMCAT (reporter)	67282	Dec. 18, 1986
	pherb-A 8.7 (hTR $\alpha$ )	40374	Sept. 29, 1987
5	peA101 (hTR $\beta$ )	67244	Oct. 22, 1986
	phRAR $\alpha$ (hRAR $\alpha$ )	40392	Nov. 20, 1987
	(* means a partial clone)		
	(pE4 & phHKA together encode complete hERR1)		

#### DESCRIPTION OF THE INVENTION

10 In one aspect, the present invention comprises steroid/thyroid hormone receptor DNA binding domain compositions that determine target gene specificity. The compositions of the invention are selected from the group consisting of GSCKV, EGCKA, EGCKG, EGCKS, EACKA,  
 15 AGRND, ASRND, PATNQ, KYDSC, KYEGK, HRDKN, PFNGD, LANKD, RGSKD, TYDGC, RSNRD, RANRN, KNEGK, KNNGE, PASNE, and PATNE.

In another aspect, the present invention is a cluster of amino acids comprised of EGxxGxxR where x is  
 20 selected from the group consisting of A, R, N, D, C, Q, E, H, I, L, K, M, F, P, S, T, W, Y, and V.

In still another aspect, the present invention is a cluster of amino acids comprised of KVEGK.

In still another aspect, the present invention  
 25 is comprised of mutant receptors selected from the group consisting of GTG8, GTG3A, GTG2, GTG1.

In still another aspect, the invention comprises a method for constructing a receptor that can activate both GRE and ERE sequences. The method  
 30 comprises introducing a point mutation into the glucocorticoid receptor DNA sequence so that the encoded glycine at the site between C<sub>3</sub> and C<sub>4</sub> is replaced with a glutamic acid. Conversely, a point mutation is introduced into the estrogen receptor DNA sequence so  
 35 the encoded glutamic acid at the site between C<sub>3</sub> and C<sub>4</sub> is replaced with a glycine.

In still another aspect, the invention comprises a substantially pure receptor protein that can activate both glucocorticoid and estrogen response element sequences.

5 In still another aspect, the invention comprises methods for converting the target gene specificity of one receptor into the target gene specificity of another. According to this aspect of the invention, target gene specificity of the gluco-  
10 corticoid receptor is converted to that of the estrogen receptor by changing three amino acids clustered in the first zinc finger. A single Gly to Glu change in this region produces a receptor with dual sequence responsiveness. Further replacement of five amino  
15 acids in the stem of the second zinc finger transforms the specificity to that of the thyroid hormone.

Still further the invention comprises novel assays for identifying functional ligands for orphan hormone receptors. These assays are especially useful  
20 since they avoid the necessity of constructing chimeric genes and proteins in order to search for ligands that can activate an orphan receptor. In addition, the assays of the invention do not require that the DNA sequences in question be sequenced to see if they  
25 belong to the GR or ER/TR subfamilies (although this can be done). Furthermore, as is done in the preferred assay of the invention, the presence of two reporter genes in the host cell, one operatively linked to a GRE and the other to a ERE, makes it possible to assay all  
30 unknown members of the steroid/thyroid receptor superfamily with a single assay system. In addition, a cocktail of ligands can be tested at once. If any of the ligands activate either of the reporters these ligands can be retested, e.g., in smaller "cocktail"  
35 groups, and then separately. This greatly increases

the efficiency of the search for ligands for the orphan receptors.

According to one assay aspect of the invention, DNA sequences are isolated that are  
5 suspected of encoding receptor proteins. These DNA sequences are transfected into a suitable receptor-deficient host cell that has been engineered to contain at least one reporter gene functionally linked to at least one operative hormone responsive element wherein  
10 the hormone response element(s) is selected from the group consisting of wild-type, engineered or synthetic glucocorticoid response element and wild-type, engineered or synthetic estrogen response element. The transfected receptor-deficient host cell (which now  
15 contains the suspected or "orphan" receptor and at least one reporter/HRE complex) is challenged with at least one candidate ligand(s) that can potentially bind with the ligand-binding domain region of the putative receptor protein encoded by the DNA sequence in  
20 question. The induction of the reporter gene is monitored by means of changes in the protein levels of the protein encoded by the reporter gene. Finally a selection is made of ligand(s) that is capable of inducing production of the protein product of the  
25 reporter gene.

In preferred assays of the invention, the transfected host cell be a CV-1 cell which will contain at least two reporter genes, each operatively linked to a different functional HRE element. In an especially  
30 preferred form, a first reporter gene will be operatively linked to wild-type, engineered or synthetic glucocorticoid response element, and a second will be operatively linked to wild-type, engineered or synthetic estrogen response element. In this form, a  
35 first reporter gene will preferably be chloramphenicol

acetyltransferase (CAT) and the second will preferably be firefly luciferase.

In another assay aspect of the invention, an assay is provided for identifying ligand(s) that  
5 activates an orphan receptor. According to this aspect of the invention, receptor-deficient host cells are provided with at least one reporter gene functionally linked to a preselected hormone response element. In addition, at least the DNA encoding the P region of the  
10 DNA binding domain of the orphan receptor is mutated, preferably by means of site directed mutagenesis, so that the mutated orphan receptor can activate the preselected hormone response element in receptor-deficient host cells. The host cells containing the  
15 preselected hormone response element functionally linked to at least one reporter gene are contacted with mutated orphan receptor, and then challenged with candidate ligand(s) which can potentially bind with the ligand-binding domain region of the mutated orphan  
20 receptor. Finally, induction of the reporter gene(s) is monitored as an indication of those ligand(s) which can activate the orphan receptor.

The compositions, methods and assays of the invention, plus preferred methods for making and using  
25 them, are described more fully in the Examples that follow.

##### EXAMPLE 1

##### Finger Module

30 Previous studies on hormone receptors have shown that amino acids throughout the entire DNA-binding domain may be important for DNA-binding (Hollenberg, et al., 1987). This example discloses which amino acids contribute to sequence recognition  
35 and are thus responsible for determining target gene specificity. Experimentally, it is important to know

what changes in the DNA binding domain are necessary, at a minimum, to allow the glucocorticoid receptor to recognize thyroid hormone and estrogen response elements. Between the human glucocorticoid receptor (hGR) and the human thyroid receptor beta (hTR $\beta$ ) less than half of the amino acids in this region are conserved (Fig. 1a). If the entire hGR DNA binding domain is replaced by that from the hTR $\beta$ , specificity is completely switched such that hybrid GTG activates only through the TRE and no longer recognizes the GRE (Thompson, et al., 1989).

In the present experiment mutant GR expression plasmids were introduced into monkey kidney CV-1 cells together with at least one reporter plasmid (e.g., one of the firefly luciferase reporter plasmids) to test its target gene specificity and transactivation function. For glucocorticoid response the luciferase coding sequence was linked to the responsive MTV-LTR (MTV-LUC plasmid) (Hollenberg, et al., 1988). For T<sub>3</sub>-responsiveness the GREs were deleted from MTV and replaced with an oligonucleotide encoding a palindromic TRE to generate reporter  $\Delta$ MTV-TRE<sub>p</sub>-LUC (Umesono, et al., 1988; Giguere, et al., 1989). Upon addition of a synthetic glucocorticoid dexamethasone, parental receptors hGR $\alpha$  and GTG elicited around 2,500 and 200 fold induction over the background level from MTV-LUC and  $\Delta$ MTV-TRE<sub>p</sub>-LUC, respectively (Fig. 2). These inductions are clearly mediated by the cognate response elements.

30

## EXAMPLE 2

### Receptor Identity: TRE Recognition

To identify amino acids that allow the receptors to discriminate between their cognate HREs, a variety of chimeric DNA binding domains were constructed. In the mutants presented in Figure 2, portions of the loops and linkers were exchanged

between the hGR and hTR $\beta$  or human retinoic acid receptor alpha (hRAR $\alpha$ ). These switches of Loop 1 (GTG7 and GTG32), most parts of the Linker (GTG38, GRGS, GTG36B, and GTG29), and Loop 2 and adjacent downstream  
5 portions (GTG6, GTG33, and GTG28). All of these switch mutants are active (88% to 7% of parental response) upon induction of a luciferase activity.

The interchangeable nature of the loops is remarkable in terms of dramatic changes in charge  
10 distribution with no change in target gene specificity. Furthermore, both small and large substitutions in the Linker regions are quite forgiving with no impact on promoter specificity. Reducing or expanding the spacing between the fingers from 15 (GR<sub>NX</sub> and GTG29),  
15 17 (GTG), 19 (GR<sub>SST</sub>) and 21 (GR<sub>SST</sub>G) is again well tolerated. From phenotypes of these mutants, it is apparent that differences in the primary structure or size found in these regions are mutually permissive even between two of the most distantly related members  
20 of the receptor superfamily. Furthermore, since none of the Loop or Linker mutants described here has changed specificity, it is concluded that these amino acids apparently are not critical in discriminating between GREs and TREs or TRE<sub>p</sub> from GREs, but rather are  
25 involved in common aspects of HRE recognition and transactivation.

The modular or interchangeable nature of large segments of the finger regions does not belie the fundamental fact that there must be sequences that  
30 determine specificity. By elimination from this series of mutants, nine amino acids in two clusters were not changed and may therefore impart specificity. The first proximal (P) region follows C<sub>3</sub> and includes the three amino acid cluster GS--V in the GR and EG--G in  
35 the TR. These are part of a 10 amino acid segment that is highly conserved and includes 6 invariant amino

acids. When these three amino acids are switched (see GTG3A in Fig. 2a and GTG36A in Fig. 2b), the resultant chimeras are nonfunctional on either MTV-LUC or  $\Delta$ MTV-PRE<sub>p</sub>-LUC. The second or distal (D) region of potential  
5 importance in specificity is a cluster of five amino acids between C<sub>5</sub> and C<sub>6</sub>; AGRND in hGR and KYEGK in hTR $\beta$ .

Indeed, elimination of these amino acids from GTG21 to produce GTG15 yields a TRE inactive phenotype (Fig.3). Based on these observations the critical  
10 double switch and mutant GTG8 (Fig. 3) was constructed which carries an almost complete hGR DNA-binding domain with only 8 hTR $\beta$ -specific amino acids. Remarkably, this chimera induces a full conversion of target gene specificity (Figs 3 and 4H). The induction of  
15 luciferase activity on the TRE<sub>p</sub> reporter by GTG8 is as efficient as GTG itself.

Thus two noncontiguous "elements" (P and D) have been localized in the hTR $\beta$  DNA-binding domain that are sufficient to impart TRE-specific recognition in  
20 the context of an otherwise normal glucocorticoid receptor. Both elements are necessary while neither alone is sufficient. Furthermore, acquisition of the TRE specificity in this change includes a complete loss of GRE responsiveness.

25

### EXAMPLE 3

#### Receptor Identity: ERE Recognition

Although all HREs contain a recognizable conserved motif, the TRE<sub>p</sub> and the palindromic vitellogenin ERE (ERE<sub>p</sub>) differ only in the spacing of  
30 what are otherwise identical half-sites (5'-TGACC-3', Fig. 1c). Furthermore, recent studies indicate that the endogenous T<sub>3</sub>R (Glass, et al., 1988) as well as the in vitro translated product of cloned  $\alpha$  and  $\beta$  TR cDNA (Thompson et al., 1989) can bind with high affinity to  
35 both ERE<sub>p</sub> as well as TRE<sub>p</sub>. Despite this relationship, the possibility that the T<sub>3</sub>R might mediate an ERE-

dependent transactivation has not been carefully evaluated. To address this issue an oligonucleotide encoding the ERE was inserted into the basal  $\Delta$ MTV promoter (Hollenberg, et al., (1988)) to make reporter  
5 plasmids  $\Delta$ MTV-ERE-LUC and  $\Delta$ MTV-ERE-CAT.

This promoter is indeed estradiol ( $E_2$ ) infusible because in CV-1 cells an efficient stimulation of CAT activity is dependent on both functional ER and the ligand  $E_2$  (Fig. 4d). The  
10 transfected HER fails to activate through the GRE (Umesono and Evans, unpublished data) but does sustain a weak activator of the TREp reporter. However, in the reciprocal experiment the GTG chimera promotes activity of the ERE reporter (Figs 3a and 4d). In contrast, hGR  
15 does not induce CAT or luciferase activity from a EREp or TREp receptor (Figs 3a and 4b). Thus, the DNA binding domain of  $hT_3R\beta$  is able to recognize both the TREp and ERE as response elements in this assay system.

Because of this close relationship between the  
20 HER and hTR mutant receptors were tested for combined ERE and TRE responsiveness to evaluate functional roles for the two specificity regions. Taking the activity of GTG as 100%, all of the TRE+ mutants in Figures 2 and 3 (GTxbag, GTsstG, GTG32, GTG36B, GTG29, GTG28,  
25 GTG21, and GTG8) showed 70% to 650% activity upon the ERE reporter (Fig. 3). Furthermore, mutants carrying hTR $\beta$  element P but lacking element D (GTG16 and GTG3A) also showed significant inductions upon ERE even though they were inactive on the TREp (Figs 3 and 4). These  
30 results demonstrate that  $hT_3R\beta$  element P, not D, determines a positive phenotype upon the common TGACC-type half sites found in ERE and TREp. Consistently all the mutants containing GR element P (HGRNX, GTG7, GTG35, GRG8, GTG6, GTG36A, GTG5) are not responsive to  
35 the ERE reporter (data not shown).

The phenotype of GTG3A (Figs 3c and 4g) has clearly revealed that replacement of three amino acids, forming element P, is sufficient to convert the identity of hGR DNA binding domain (GRE<sup>+</sup>, ERE<sup>-</sup>, TRE<sup>-</sup>) into that of ER (GRE<sup>-</sup>, ERE<sup>+</sup>, TRE<sup>-</sup>). It is noteworthy that this is a complete conversion; that is, this mutant is negative upon MTV and only positive upon ERE. The ERE responsiveness of mutant GTG3A is not restricted to the modified MTV promoter. For example, ERE-TK-LUC reporter is also regulated by GTG3A while the parental TK-LUC that lacks an oligonucleotide encoding ERE is not induced (unpublished observations).

#### EXAMPLE 4

##### Receptor Identity: Dual Specificity

The data presented herein have shown that element P, located in the base of Finger 1 and part of the adjacent Linker specifies the GRE-ERE responsiveness. This element includes three amino acid differences between hGR (GSCKV) and hT<sub>3</sub>R $\beta$ . Interestingly hT<sub>3</sub>R $\beta$  and hER (EGCKA), both of which are active upon ERE, share almost identical structures when it comes to this element (Fig. 1a), indicating that these amino acid sequences are important for the recognition of ERE.

One trend of these results is that by imparting a new specificity upon a DNA-binding domain, the previous binding specificity is simultaneously lost. To determine whether individual amino acids play different roles with regard to acquisition or suppression of HRE specificity, the activity of single paired and triple mutants was examined. Although the triple mutant (GTG3A) selectively recognizes the ERE, the double mutant (GTG2) is active upon both MTV and ERE reporter (Fig. 3c and 4f). This induction is dependent on the HRE since this receptor fails to activate either  $\Delta$ MTV or TREp promoter (Fig. 4). An

examination of the phenotype of this mutant indicates that the last glycine in the T<sub>3</sub>R $\beta$  P element seems to be involved in a suppression of the GRE<sup>+</sup> without a substantial impact on ERE recognition.

5           Based on this result the question was asked whether a single amino acid substitution would be sufficient to impart a recognizable change on receptor phenotype. Remarkably, by substituting the glucocorticoid receptor glycine or an estrogen receptor  
10 glutamic acid between C<sub>3</sub> and C<sub>4</sub> (GTG1) a receptor with dual specificity is produced. This single amino acid change leaves GRE recognition normal but fosters clear recognition of the ERE. As with GTG2 mutant, these inductions are dependent on either GRES or ERES (Fig:  
15 3c and 4e). However, because all of these mutants lack the T<sub>3</sub>R $\beta$  D element, they are completely inactive on the TREp.

#### EXAMPLE 5

##### The P and D Elements

20           As those skilled in the art will appreciate, the results presented in the previous Examples provide a number of unexpected conclusions concerning the mechanisms by which the nuclear receptors identify their appropriate response elements. First, the  
25 putative loops of the two zinc fingers can be exchanged between receptors without altering specificity. Second, two distinct regions, P and D, outside the loops, are critical for sequence recognition. Third, different amino acids may be involved in acquisition  
30 and loss of HRE responsiveness. Because of this, it has been possible via a single amino acid change to create a receptor with dual GRE and ERE recognition.

          It is important to understand that these results do not imply that the amino acids in the loops  
35 are not critical for sequence specific binding; rather our results show that the amino acids in the loops are

not critical in identifying the differences between response elements. Thus, it may be presumed that the commonality of loop function indicates that they mediate recognition of common aspects of HRE structure. In contrast, the P and D elements would be involved in recognizing the variant nucleotides. This is consistent with the observation that HREs are composed of a common core sequence that can change in only a restricted number of nucleotide positions. This would suggest a putative topographical alignment between the HRE and the zinc finger such that the variable region of the HRE would always align with the P element of the finger. It can therefore be presumed that amino acids in this element make specific contacts with at least one of the variable positions in the pentameric HRE.

In addition to primary sequence recognition there is a need to discriminate half-site spacing (ERE vs. TRE; Fig. 1c). As summarized in Table 1, our results indicate that the first element (P) specifies the primary nucleotide sequence of the half sites, while the second element (D) is important for the determination of the half-site spacing. In other words the second element in the hGR and hER restricts recognition to HREs with three gap nucleotides.

In respect to the amino acid sequence of the first element, all members of this receptor superfamily can be classified into either GR or ER subfamily (Table 2). The GR subfamily includes four members (GR, MR, PR, and AR (Evans, 1988); Lubahn, et al., 1988); Ham, et al., 1988), and all of them are able to recognize GREs, although physiological effects of each hormone are quite different (Ham, et al., 1988). The other members constitute the ER/TR subfamily (ER,  $T_3R\alpha$ ,  $T_3R\beta$ ,  $RAR\alpha$ ,  $RAR\beta$ ,  $VD_3R$ , NGFI-B (Milbrandt, 1988), TR-2 (Chang, et al., 1988), v-erbA, ear2 (Miyajima, et al., 1988), ear3 (Miyajima, et al., 1988), knirps (Nauber, et al.,

1988), *knirps*-related (Oro, et al., 1988b), ERR1 and ERR2 (for reference, see Evans, 1988) with a slight variation. The members of this subfamily may recognize ERE, TREp, or a palindromic pair of TGACC sequences  
5 separated by five or more gap nucleotides because of the critical glutamic acid residue following C<sub>3</sub>. In support of this model, our group at the Salk Institute for Biological Studies has shown that retinoic acid receptor can bind to and activate transcription through  
10 TREp.

Compared to the structural conservation of the first element, the second element is quite divergent. According to our hypothesis the second element need not bind directly to DNA but rather may determine spatial  
15 configuration of the half-sites via protein-protein interaction. One possibility is that it may represent a dimerization interface. This assumption is consistent with recent reports that the receptor DNA binding domain by itself seems to contain a  
20 dimerization signal (Kumar, et al., 1988; Tsai, et al., 1988).

DETAILED DESCRIPTION OF THE DRAWINGS

FIGURE 1. a) Comparison of amino acid sequences among the DNA binding domains of hGR, hT<sub>3</sub>R $\beta$ , and hER (for reference, see Evans, 1988). Upper numbers (1 to 9) correspond to the invariant nine cysteines found in the receptor DNA binding domains. Number adjacent to the sequences indicate amino-acid positions of each receptor. Colons show the identity of amino acids between hGR and hT<sub>3</sub>R $\beta$  or hT<sub>3</sub>R $\beta$  and hER. The hT<sub>3</sub>R $\beta$  DNA binding domain contains two extra amino acids in the middle of the domain. b) Predicted zinc fingers based on those for rat GR18. Numbers 1 to 9 for cysteines are as in Fig 1a. Conserved amino acids in hGR, hT<sub>3</sub>R $\beta$ , and hER are shown by one letter amino-acid code. Dots represent variable amino acids among these receptors. Two zinc ions (Zn) are chelated in a tetrahedral coordination by two clusters of four cysteines (C<sub>1</sub> to C<sub>4</sub> and C<sub>5</sub> to C<sub>8</sub>), forming two "zinc fingers" (Finger 1 and Finger 2). The two fingers are separated by 15 (hGR and hER) or 17 (hT<sub>3</sub>R $\beta$ ) amino acids consisting of Linker between the fingers. c) Structures of optimized hormone response elements for GR (GRE), ER (ERE), and T<sub>3</sub>R (TRE) (See Green and Chambon, 1988; Klock et al., 1987; and Glass et al., 1988). Each arrow indicates a "half site" of the HREs. These HREs consist of a palindromic pair of the half sites as shown by the arrows. Both GRE and ERE contain three gap nucleotides (nnn) between the half sites, but no such nucleotide is found in TREp (---). Dots in ERE and TREp indicate different nucleotides from those of GRE. Accordingly, ERE and TREp contain the same half site sequence.

FIGURE 2. Transactivation of luciferase reporter plasmids by mutant receptors. a) The amino acid sequence of a parental hGR $\alpha$  DNA binding domain

is presented. The hGRnx contains the wild-type hGR DNA binding domain flanked by NotI and XhoI sites in the cDNA. Numbers 1 to 9 are as in Fig. 1a. Substituted or inserted amino acids in mutants GRxba and GRsst are shown. b) Structures of chimeric GR DNA binding domains carrying local hT<sub>3</sub>R $\beta$  (GTG23, GTG7, GTG3A, and GTG6) or hRAR $\alpha$  (GRG8) sequences. Changed amino acids are presented. Mutants are designated after the composition of their DNA binding domains; GTG23 stands for a mutant GR which has a DNA binding domain composed of both hGR and hT<sub>3</sub>R $\beta$  sequences, and contains 23 different amino acids from the wild-type hGR sequence. c) The amino acid sequence of the hT<sub>3</sub>R $\beta$  DNA binding domain in a hybrid receptor GTG is shown: The GTG is a hybrid GR whose DNA binding domain has been replaced by that of hT<sub>3</sub>R $\beta$ . As in a) changed amino acids are presented for GTxbaG and GTsstG. d) Chimeric hT<sub>3</sub>R $\beta$  DNA binding domains carrying hGR sequences indicated by one letter amino-acid code. Each receptor expression plasmid was cotransfected into CV-1 cells with either glucocorticoid (MTV-LUC) or thyroid hormone ( $\Delta$ MTV-TREp-LUC) responsive reporter plasmids, and the cells were cultured in the absence or presence of 100nM dexamethasone for 36 hours. Transactivation function of these receptors was judged by the induced luciferase activity from the reporter plasmids quantified as percentage of HGRNX and GTG activities upon MTV-LUC (MTV) (2,500 fold) and  $\Delta$ MTV-TREp-LUC (TREp) (200 fold), respectively. The activity below the background induction level (6 fold for MTV and two fold for TREp) is indicated as -. For the activity of GTG18 on TREp, the "(2)" indicates that the induction is not dependent on TREp.

Figure 2 Methods. hGRnx10 and GTG14 were constructed using known and previously published

methods. Mutant cDNAs encoding DNA binding domains of GRxba, GTG7, GTG3B, GRG8, GTG6, and GTG3A were obtained through an oligonucleotide-directed mutagenesis (Kunkel, et al., 1985) of the NotI-XhoI DNA fragment encoding the hGRnx DNA binding domain. Similarly, those for GTxbaG, GTG32, GTG36B, GTG29, GTG33, and GTG36A were made by exchanging the NotI-XhoI fragment for the hT<sub>3</sub>R<sub>8</sub> DNA binding domain. Mutants GRsst and GTsstG cDNAs contain a SstI linker (8-mer, New England Biolabs) at filled-in XbaII sites of GRxba and GTxbaG, respectively. GTG23 and GTG18 were obtained by exchanging small NotI-XbaI fragments between GRxba and GTxbaG. Each of the NotI-XhoI cDNA fragments encoding mutant DNA binding domains was ligated with a large NotI-XhoI fragment obtained from PRShGRnx10. To make GTG28, ClaI site was introduced into hT<sub>3</sub>R<sub>8</sub>nx14 DNA binding domain cDNA (corresponding to amino acids "ID" in the loop of the Finger 2. Because the hGRnx cDNA has the ClaI site at this position, the NotI-ClaI fragment of the hGRnx cDNA was replaced by that of hT<sub>3</sub>R<sub>8</sub>nx cDNA. All mutations were confirmed by the nucleotide sequencing. Construction of reporter plasmids MTV-LUC7 and ΔMTV-TREp-LUC21 was done using previously published methods. Receptor expression plasmid (1 μg), reporter plasmid (5 μg), β-galactosidase reference plasmid (5 μg), and carrier plasmid pGEM4 (9 μg) were cotransfected. Transfection of CV-1 cells (Umesono, et al., 1988) and an assay for the luciferase activity were done using published methods (de Wet, et al., 1987) except that the reference plasmid PRSVβGAL was replaced by pRAS-βGAL which contains a human c-Ha-ras promoter (Ishii, et al., 1985) linked to the coding sequence of β-galactosidase in a pUC-derivativ plasmid (pUCGALpA, kindly provided by Dr. Richard J. Rickles), and phenol red in the culture

media was omitted after introduction of the plasmids into the cells.

FIGURE 3. Identification of two distinct elements specifying the TREp+ and ERE+ phenotypes.

- 5 Two parental DNA binding domains are presented by bold letters. In GTG identical amino acids to those in hGR are indicated by dots. Similarly, only different amino acids in mutant DNA binding domains from those of hGR are shown. The two regions
- 10 (element P and D) are marked by boxes. Nomenclature of the mutants and numbers are the same as in Fig. 2. Mutant receptors were tested for transactivation function in the presence of one of the luciferase reporters carrying GRES (MTV-LUC), TREp ( $\Delta$ MTV-TREp-LUC), or ERE ( $\Delta$ MTV-ERE-LUC) after transient
- 15 expression in CV-1 cells ( $\pm$  100nM dexamethasone for 36 hours). Weak stimulation (2) by GTG15 on TREp is due to higher background activity by this mutant, and the 2% induction is not dependent on TREp. 100%
- 20 induction of the luciferase activity by GTG on  $\Delta$ MTV-ERE-LUC (ERE) is 10 fold, and - indicates no induction. Relative activities by TRE+ mutants shown in Fig. 2 on ERE reporter are as follows: GTG32 (90%), GTG36B (140%), GTG29 (70%), GTG33 (380%),
- 25 GTG28 (650%).

Figure 3 Methods. An estrogen responsive reporter plasmid  $\Delta$ MTV-ERE-LUC was constructed as follows: an oligonucleotide encoding a palindromic ERE (5'-TCAGGTCACAGTGACCTGA-3') (see Glass, et al.,

30 1988) was inserted into the unique HindIII site of the  $\Delta$ MTV-CAT plasmid, in which major GRES between position -190 and -88 of MTV-LTR were deleted; this generated  $\Delta$ MTV-ERE-CAT; the CAT gene was subsequently replaced with the luciferase gene obtained from pSVO-

35 A/L-A  $\Delta$ 5' (de Wet, et al., 1987), giving  $\Delta$ MTV-ERE-LUC. Mutant GTG21 is made from GTG32 by introducing

the *Cla*I site as in GTG28 (Fig. 2d). A small *Not*I-*Cla*I fragment of hGR $\alpha$  was exchanged by that of GTG32-*Cla*I. GTG15 and GTG8 were obtained through site-directed mutagenesis (Kunkel, et al., 1985) of the cDNAs encoding GTG21 and GTG3A DNA binding domains, respectively. Similarly GTG2 and GTG1 were made from hGR $\alpha$ . Transfection and an assay of the luciferase activity were as in Fig. 2.

FIGURE 4. Induction of CAT activities by mutant receptors from the basal  $\Delta$ MTV-CAT ( $\Delta$ M), T3-responsive  $\Delta$ MTV-TREp-CAT (TREp), and estrogen-responsive  $\Delta$ MTV-ERE-CAT (ERE) reporters. Together with one of the reporters, indicated receptor expression plasmids from a) to h) were transfected into CV-1 cells. The receptors were activated by adding 100nM of dexamethasone (D) or 17 $\beta$ -estradiol (E<sub>2</sub>) for 36 hours. The "-" symbol indicates that the solvent ethanol was added. Structures of hGR $\alpha$ , GTG, GTG8, GTG3A, GTG2, and GTG1 were presented in Figs. 2 and 3. The notation "no receptor" indicates that an expression plasmid encoding hT<sub>3</sub>R $\beta$  in the reverse orientation was cotransfected. hER; human estrogen receptor. From e) to h), changed amino acids are shown in a schematic figure for hGR zinc fingers.

The calculated % conversions in the CAT assays are a)  $\Delta$ M (-) 0.4, (D) 0.5, TREp (-) 0.4, (D) 0.6, ERE (-) 0.6, (D) 1.0, b)  $\Delta$ M (-) 0.4, (D) 0.7, TREp (-) 0.3, (D) 0.8, ERE (-) 0.4, (D) 1.2, c)  $\Delta$ M (-) 1.8, (E<sub>2</sub>) 1.6, TREp (-) 1.6, (E<sub>2</sub>) 7.0, ERE (-) 1.8, (E<sub>2</sub>) 78, d)  $\Delta$ M (-) 1.4, (D) 4.6, TREp (-) 1.1, (D) 74, ERE (-) 1.9, (D) 72, e)  $\Delta$ M (-) 0.5, (D) 1.3, TREp (-) 0.6, (D) 1.4, ERE (-) 1.2, (D) 20, f)  $\Delta$ M (-) 0.8, (D) 1.8, TREp (-) 0.9, (D) 3.5, ERE (-) 1.3, (D) 96, g)  $\Delta$ M (-) 0.5, (D) 0.7, TREp (-) 0.5, (D) 0.6, ERE (-) 1.0, (D) 88, h)  $\Delta$ M (-) 0.7, (D) 4.3, TREp (-) 0.7, (D) 87, ERE (-) 1.0, (D) 95.

Figure 4 Methods. Reporter plasmids  $\Delta$ MTV-CAT (Hollenberg, et al., 1988),  $\Delta$ MTV-TREp-CAT (TRE-p1MCAT (Umesono, et al., 1988; Thompson and Evans, 1989),  $\Delta$ MTV-ERE-CAT (see legend for Fig. 3), and an  
5 expression plasmid for hER35 were previously described. CV-1 cell transfection has been carried out as described in the legend for Fig. 2 except that the luciferase reporters were replaced by the CAT  
10 cell extracts corresponding to 30 units of  $\beta$ -galactosidase activity (Herbomel, et al., 1984) were incubated for 3 hours. Calculation of % conversion for CAT activity was carried out as previously described (Thompson and Evans, 1989).

SPECIFICATION SUMMARY

From the foregoing description, one of ordinary skill in the art can understand that the present invention discloses steroid/thyroid hormone receptor DNA binding domain compositions that

10 determine target gene specificity. The invention further discloses methods converting the target gene specificity of one receptor into the target gene specificity of another. Still further the invention discloses novel assays for identifying functional

15 ligands for putative or "orphan" hormone receptors. These assays are especially useful since they avoid the necessity of constructing chimeric genes and proteins in order to search for ligands that can activate an orphan receptor.

20 Without departing from the spirit and scope of this invention, one of ordinary skill can make various changes and modifications to the invention to adapt it to various usages and conditions. As such, these changes and modifications are properly,

25 equitable, and intended to be, within the full range of equivalence of the following claims.

0 WHAT IS CLAIMED IS:

1. Element P amino acids selected from the group consisting of GSCKV, EGCKA, EGCKG, EGCKS, and EACKA.

5 2. Element D amino acids selected from the group consisting of AGRND, ASRND, PATNQ, KYDSC, KYEGK, HRDKN, PFNGD, LANKD, RGSKD, TYDGC, RSNRD, RANRN, KNEGK, KNGGE, PASNE, PATNE, AGRND, ASRND, PATNQ, KYDSC, KYEGK, HRDKN, PFNGD, LANKD, RGSKD, TYDGC, RSNRD, RANRN, KNEGK, KNGGE, PASNE, and PATNE.

10 3. Mutant receptors selected from the group consisting of GTG8, GTG3A, GTG2, GTG1.

4. A method for constructing a receptor that can activate both GRE and ERE sequences, said method comprising introducing a point mutation into: (A) the  
15 glucocorticoid receptor DNA sequence so that the encoded glycine at the site between C<sub>3</sub> and C<sub>4</sub> is replaced with a glutamic acid, or (B) the estrogen receptor DNA sequence so that the encoded glutamic acid at the site between C<sub>3</sub> and C<sub>4</sub> is replaced with a  
20 glycine.

5. A substantially pure receptor protein that can activate both glucocorticoid and estrogen response elements.

6. A substantially pure receptor protein  
25 according to Claim 5 wherein said protein is produced by the method of Claim 4.

7. A method for identifying functional ligand(s) for an orphan receptor protein, said method comprising: (A) isolating DNA sequences suspected of  
30 encoding receptor protein; (B) transfecting into a suitable receptor-deficient host cell: (1) the DNA sequences from step A, and (2) at least one reporter gene functionally linked to at least one operative hormone response element wherein said hormone  
35 response element(s) is selected from the group

consisting of wild-type, engineered or synthetic glucocorticoid response element and wild-type, engineered or synthetic estrogen response element; (C) challenging the transfected host cell from step B with candidate ligand(s) which can potentially bind with the ligand-binding domain region of the orphan receptor protein encoded by the DNA sequence of step A; and (D) monitoring induction of the reporter gene(s).

10           8. A method for identifying functional ligand(s) for an orphan receptor protein, said method comprising: (A) isolating DNA sequences suspected of encoding receptor proteins; (B) transfecting into a suitable receptor-deficient host cell: (1) the DNA  
15 sequences from step A, (2) at least one reporter gene functionally linked to at least one operative hormone responsive element wherein the hormone response element(s) is selected from the group consisting of wild-type, engineered or synthetic glucocorticoid  
20 response element, and (3) at least one reporter gene functionally linked to at least one operative hormone response element wherein the hormone response element(s) is selected from the group consisting of wild-type, engineered or synthetic estrogen response  
25 element; (C) challenging the transfected host cell from step B with candidate ligand(s) which can potentially bind with the ligand-binding domain region of the orphan receptor protein encoded by the DNA sequence of step A; and (D) monitoring induction  
30 of the reporter gene(s).

          9. A method for identifying functional ligand(s) for an orphan receptor protein (ORP), said method comprising: (A) identifying at least one functional hormone response element that is activated  
35 by th orphan r ceptor protein (ORP); (B) contacting said orphan receptor protein (ORP) in receptor-

deficient host cells with at least one reporter gene  
operatively linked to said functional hormone  
response element identified in step A; challenging  
said host cells from step B with candidate ligand(s)  
5 which can potentially bind with the ligand-binding  
domain region of said orphan receptor protein (ORP);  
and (D) monitoring induction of the reporter gene(s).

10. A method according to Claim 9 A wherein  
said functional hormone response element is  
10 identified by (A) determining the amino acid sequence  
of at least the hormone response element determining  
portion of the DNA binding domain of said orphan  
receptor protein, and (B) identifying a hormone  
response element that is activated by the amino acids  
15 determined in step A.

11. A method for identifying functional  
ligand(s) for an orphan receptor protein in a cell  
wherein said cell contains (A) a DNA sequence  
suspected of encoding an orphan receptor protein, (B)  
20 at least one reporter nucleic acid sequence  
functionally linked to an operative hormone response  
element wherein the hormone response element is  
selected from the group consisting of wild-type,  
engineered or synthetic glucocorticoid response  
25 element, and (C) at least one reporter nucleic acid  
sequence functionally linked to an operative hormone  
response element wherein the hormone response element  
is selected from the group consisting of wild-type,  
engineered or synthetic estrogen response element;  
30 said method comprising challenging the receptor-  
deficient cell with at least one candidate ligand and  
monitoring induction of the reporter nucleic acid  
sequence(s).

12. A method of any of Claims 7-11 wherein  
35 said cell is a CV-1 cell.

13. A method according to any of Claims 7-11 wherein the reporter gene is selected from the group consisting of a chloramphenicol acetyltransferase (CAT) gene and a firefly luciferase gene.

5           14. A method for identifying a ligand(s) that activates an orphan receptor comprising: (A) providing in receptor-deficient host cells at least one reporter gene functionally linked to a  
10           preselected hormone response element; (B) mutating at least the DNA encoding the P region of the DNA binding domain of the orphan receptor so that the mutated orphan receptor thus produced can activate the preselected hormone response element from step A;  
15           (C) contacting receptor-deficient cells from step A with mutated orphan receptor from step B; (D) challenging said cells from step C with candidate ligand(s) which can potentially bind with the ligand-binding domain region of said mutated orphan receptor; and (E) monitoring induction of the  
20           reporter gene(s).

          15. A method according to Claim 14 B wherein said P region is mutated by sight directed mutagenesis.

## AMENDED CLAIMS

[received by the International Bureau on 17 September 1990 (17.09.90)  
original claims 7 and 8 amended; other claims unchanged (2 pages)]

1. Element P amino acids selected from the group consisting of GSCKV, EGCKA, EGCKG, EGCKS, and EACKA.
2. Element D amino acids selected from the  
5 group consisting of AGRND, ASRND, PATNQ, KYDSC, KYEGK, HRDKN, PFNGD, LANKD, RGSKD, TYDGC, RSNRD, RANRN, KNEGK, KNGGE, PASNE, PATNE, AGRND, ASRND, PATNQ, KYDSC, KYEGK, HRDKN, PFNGD, LANKD, RGSKD, TYDGC, RSNRD, RANRN, KNEGK, KNGGE, PASNE, and PATNE.
- 10 3. Mutant receptors selected from the group consisting of GTG8, GTG3A, GTG2, GTG1.
4. A method for constructing a receptor that can activate both GRE and ERE sequences, said method comprising introducing a point mutation into: (A) the  
15 glucocorticoid receptor DNA sequence so that the encoded glycine at the site between C<sub>3</sub> and C<sub>4</sub> is replaced with a glutamic acid, or (B) the estrogen receptor DNA sequence so that the encoded glutamic acid at the site between C<sub>3</sub> and C<sub>4</sub> is replaced with a  
20 glycine.
5. A substantially pure receptor protein that can activate both glucocorticoid and estrogen response elements.
6. A substantially pure receptor protein  
25 according to Claim 5 wherein said protein is produced by the method of Claim 4.
7. A method for identifying functional  
ligand(s) for an orphan receptor protein, said method comprising: (A) isolating DNA sequences suspected of  
30 encoding receptor protein; (B) introducing into a suitable receptor-deficient host cell: (1) the DNA sequences from step A, and (2) at least one reporter gene functionally linked to at least one operative hormone response element wherein said hormone  
35 response element(s) is selected from the group

consisting of wild-type, engineered or synthetic glucocorticoid response element and wild-type, engineered or synthetic estrogen response element; (C) challenging the transfected host cell from step B with candidate ligand(s) which can potentially bind with the ligand-binding domain region of the orphan receptor protein encoded by the DNA sequence of step A; and (D) monitoring induction of the reporter gene(s).

10           8. A method for identifying functional ligand(s) for an orphan receptor protein, said method comprising: (A) isolating DNA sequences suspected of encoding receptor proteins; (B) introducing into a suitable receptor-deficient host cell: (1) the DNA  
15 sequences from step A, (2) at least one reporter gene functionally linked to at least one operative hormone responsive element wherein the hormone response element(s) is selected from the group consisting of wild-type, engineered or synthetic glucocorticoid  
20 response element, and (3) at least one reporter gene functionally linked to at least one operative hormone response element wherein the hormone response element(s) is selected from the group consisting of wild-type, engineered or synthetic estrogen response  
25 element; (C) challenging the transfected host cell from step B with candidate ligand(s) which can potentially bind with the ligand-binding domain region of the orphan receptor protein encoded by the DNA sequence of step A; and (D) monitoring induction  
30 of the reporter gene(s).

          9. A method for identifying functional ligand(s) for an orphan receptor protein (ORP), said method comprising: (A) identifying at least one functional hormone response element that is activated  
35 by th orphan receptor protein (ORP); (B) contacting said orphan receptor protein (ORP) in receptor-

V. ☐ OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE<sup>1</sup>

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. ☐ Claim numbers \_\_\_\_\_ because they relate to subject matter<sup>1,2</sup> not required to be searched by this Authority, namely:

2. ☐ Claim numbers \_\_\_\_\_, because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out<sup>1,3</sup>, specifically:

3. ☐ Claim numbers \_\_\_\_\_, because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. ☐ OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING<sup>4</sup>

This International Searching Authority found multiple inventions in this international application as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. ☐ As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

## Remark on Protest

☐ The additional search fees were accompanied by applicant's protest.

☐ No protest accompanied the payment of additional search fees.
